Approximate optimality and approximate duality in nonsmooth composite vector optimization

THANATCHAPORN SIRICHUNWIJIT¹, RABIAN WANGKEEREE¹,² and NITHIRAT SISARAT¹

ABSTRACT. This paper concentrates on studying a nonsmooth composite vector optimization problem (P for brevity). We employ a fuzzy necessary condition for approximate (weakly) efficient solutions of a non-convex and nonsmooth cone constrained vector optimization problem established in [Choung, T. D. Approximate solutions in nonsmooth and nonconvex cone constrained vector optimization Ann. Oper. Res. (2020), https://doi.org/10.1007/s10479-020-03740-3.] and the a chain rule for generalized differentiation to provide a necessary condition which exhibited in a Fritz-John type for approximate (weakly) efficient solutions of (P). Sufficient optimality conditions for approximate (weakly) efficient solutions to (P) are also provided by means of proposing the use of (strictly) approximately generalized convex composite vector functions with respect to a cone. Moreover, an approximate dual vector problem to (P) is given and strong and converse duality assertions for approximate (weakly) efficient solutions are proved.

1. INTRODUCTION

Due to the increased complexity of the optimization problems that have many questions of theoretical and computational interest, the study of problems that encompass as special instances of the already remedied ones are of great concern. In this paper, we lay out a unified framework for examining optimization problems by viewing a composite vector optimization problem of the form:

\[(P) \quad \min_K \{ (f \circ F)(x) \mid x \in \Omega, \ (g \circ G)(x) \in -S \}, \]

where \(F : X \to W, G : X \to V, f : W \to Y \) and \(g : V \to Z \) are vector functions between finite-dimensional spaces, \(K \subset Y \) is a pointed (i.e., \(K \cap (-K) = \{0\}\)) closed convex cone, \(S \subset Z \) is a nonempty closed convex cone and \(\Omega \subset X \) is a nonempty closed set. Hence, we always assume that the topological interior of \(K \) is nonempty (i.e., \(\text{int } K \neq \emptyset \)) and \(F, G, f, g \) are locally Lipschitz at the corresponding points under consideration. The modeling of problems as (P) covers broad classes of various optimization problems such as conic vector optimization problems, (standard) multiobjective/vector optimization problems, multiobjective approximation problems [8, 23, 42], and many optimization problems manufactured in practical fields like engineering or economics and finance. Over the last couple of decades, issues related to optimality conditions and duality for (weakly) efficient solutions of the model problem (P) have been extensively investigated in the literature; see [1, 2, 7, 8, 23, 31, 32, 36] and other references therein. For other results concerning on optimality conditions and duality in both smooth/nonsmooth multi-objective/vector optimization problems involving convex/generalized convex functions, we refer the readers to [3, 5, 6, 24, 25, 38, 41] and other references therein.
As known to all, from the computational point of view, approximate solutions in optimization problems occur naturally by way of stopping numerical procedures after a finite number of steps. Moreover, in general, optimization problems do not necessarily have the exact solutions whereas approximate ones exist under very mild hypotheses. Therefore, it is significant to study approximate solutions instead to optimization problems from both points of view, and so, many authors have turned their more and more attention to this topic; see [10, 12, 15, 16, 17, 18, 19, 20, 21, 26, 27, 28, 40] and the references therein. The interested reader is referred to [9, 13, 14] for more information on optimality conditions and duality for approximate (weakly) efficient solutions in connection with the multiobjective/vector optimization. With this aim in view, in this paper, we continue a broad framework for examining approximate (weakly) efficient solutions for the problem (P) which, to our knowledge, have not been investigated yet. It should be noted here that the most notion of approximate solutions for optimization problems involving nonconvex functions is that of approximate-quasi solutions which can be regarded as a local concepts of approximate solutions in view of Ekeland’s variational principle [11]. This notion has also been extended to vector optimization problems, see e.g., [26, 28]. In what follows, let us now recall the concept of (weak) \(e\)-quasi efficient solutions for the problem (P).

**Definition 1.1.** Let \(e \in K\) and \(\bar{x} \in C := \{x \in \Omega \mid (g \circ G)(x) \in -S\}\).

(i) One say that \(\bar{x}\) is a weak \(e\)-quasi efficient solution of problem (P), denoted by \(\bar{x} \in e - S^{\text{w}}(P)\), whenever

\[
\forall x \in C, \ (f \circ F)(x) - (f \circ F)(\bar{x}) + \|x - \bar{x}\|e \notin -\text{int } K.
\]

(ii) One say that \(\bar{x}\) is an \(e\)-quasi efficient solution of problem (P), denoted by \(\bar{x} \in e - S(P)\), whenever

\[
\forall x \in C, \ (f \circ F)(x) - (f \circ F)(\bar{x}) + \|x - \bar{x}\|e \notin -\text{K}\{0\}.
\]

Note also that in case of \(e := 0\), the above-defined (weak) \(e\)-quasi efficient solution collapses to (weak) Pareto solution defined as in [22, 29, 39].

The aim of this paper is to study a class of approximate (weakly) efficient solutions, i.e., (weak) \(e\)-quasi efficient solutions to a nonsmooth composite vector optimization problem (P). We apply a fuzzy necessary condition [9, Theorem 3.2] for approximate (weakly) efficient solutions of a nonconvex and nonsmooth cone constrained vector optimization problem, which was recently established based on the approximate extremal principle and the a chain rule for generalized differentiation [34, 35] to achieve a necessary condition which exhibited in a Fritz-John type for approximate (weakly) efficient solutions of (P). This formulation is expressed in terms of the limiting/Mordukhovich subdifferential. Sufficient optimality conditions for approximate (weakly) efficient solutions to (P) are also provided by means of proposing the use of (strictly) approximately generalized convex composite vector functions with respect to a cone. According to approximate optimality conditions, we state an approximate dual vector problem to (P) and explore strong and converse duality assertions for approximate (weakly) efficient solutions.

The rest of paper is organized as follows. The next section presents some notations and preliminaries. Sect. 3 is devoted to establishing necessary and sufficient optimality conditions for a approximate (weakly) efficient solutions of a nonsmooth composite vector optimization problem (P). Finally, Sect. 4 explores duality relations between approximate (weak) efficient solutions of the problem (P) and its dual one in the sense of Mond and Weir.
In this section, we recall some notations, basic definitions, and preliminary results which will be utilized throughout the paper. Now, all spaces are assumed to be finite-dimensional equipped with norms $\| \cdot \|$. A closed unit ball in $X$ is denoted by $B_X$. The topological closure and the topological interior of a set $\Omega \subset X$ are denoted by $\text{cl} \, \Omega$ and $\text{int} \, \Omega$, respectively. As usual, the dual cone of $\Omega \subset X$ is the set $\Omega^+ := \{ x^* \in X \mid \langle x^*, x \rangle \geq 0, \forall x \in \Omega \}$. Also, for $n \in \mathbb{N} := \{1, 2, \ldots \}$, we denote by $\mathbb{R}^n_+$ the nonnegative orthant of $\mathbb{R}^n$. For a product space $X \times Y$, its norm is defined by $\|(x, y)\| = \|x\| + \|y\|$ for $x \in X$ and $y \in Y$.

Given a set-valued mapping (or multifunctions) $H : X \rightrightarrows X$, with values $H(x) \subset X$ in the collection of all the subsets of $X$, we denote by

$$\limsup_{x \to \bar{x}} H(x) := \{x^* \in X \mid \exists \{x_n\} \to x_0, \ x_n \to x^* \mathrm{with} \ x_n^* \in H(x_n) \ \mathrm{for \ all} \ n \in \mathbb{N} \},$$

the sequential Painlevé-Kuratowski upper/outer limit of $H$ as $x \to \bar{x}$.

Let $\Omega \subset X$ be closed around $x \in \Omega$, i.e., there is a neighborhood $U$ of $\bar{x}$ such that $\Omega \cap \text{cl} \, U$ is closed. The Fréchet normal cone to $\Omega$ at $x \in \Omega$ is defined by

$$\hat{N}(\bar{x}; \Omega) := \left\{ x^* \in X \mid \limsup_{x \to \bar{x} \atop x \in \Omega} \frac{\langle x^*, x - \bar{x} \rangle}{\| x - \bar{x} \|} \leq 0 \right\},$$

where $x \xrightarrow{\Omega} \bar{x}$ stands for $x \to \bar{x}$ with $x \in \Omega$. If $x \notin \Omega$, we stipulate that $\hat{N}(x; \Omega) := \emptyset$.

The Mordukhovich/limiting normal cone $N(\bar{x}; \Omega)$ to $\Omega$ at $\bar{x} \in \Omega$ is obtained from Fréchet normal cones by taking the sequential Painlevé-Kuratowski upper limits as:

$$\tag{2.1} N(\bar{x}; \Omega) := \limsup_{x \xrightarrow{\Omega} \bar{x}} \hat{N}(x; \Omega).$$

If $x \notin \Omega$, we put $N(x; \Omega) := \emptyset$.

For an extended real-valued function $\varphi : X \to \overline{\mathbb{R}} := \mathbb{R} \cup \{+\infty\}$, the effective domain and the epigraph are respectively defined by

$$\text{dom} \, \varphi := \{ x \in X \mid \varphi(x) < +\infty \} \ \text{and} \ \text{epi} \, \varphi := \{ (x, \mu) \in X \times \mathbb{R} \mid \mu \geq \varphi(x) \}.$$

The Mordukhovich/limiting subdifferential and the Fréchet subdifferential of $\varphi$ at $\bar{x} \in \text{dom} \, \varphi$ are defined, respectively, by

$$\partial \varphi(\bar{x}) := \{ x^* \in X \mid (x^*, -1) \in N((\bar{x}, \varphi(\bar{x})); \text{epi} \, \varphi) \},$$

and

$$\hat{\partial} \varphi(\bar{x}) := \{ x^* \in X \mid (x^*, -1) \in \hat{N}((\bar{x}, \varphi(\bar{x})); \text{epi} \, \varphi) \}.$$

If $\bar{x} \notin \text{dom} \, \varphi$, then one puts $\partial \varphi(\bar{x}) := \hat{\partial} \varphi(\bar{x}) := \emptyset$. It is worth noting [34, 35] that if $\varphi$ is a convex function, the above-defined subdifferential coincides with the subdifferential in the sense of convex analysis [37].

For any vector function $f : X \to Y$ we can associate $f$ with a scalarization function with respect to some $y^* \in Y$ defined by

$$\langle y^*, f(x) \rangle := \langle y^*, f(x) \rangle, \ x \in X.$$

We close the section by the following results that are needed for our study.

**Lemma 2.1.** Let $y^* \in \mathbb{R}^n$, and let $f : X \to \mathbb{R}^n$ be Lipschitz continuous around $\bar{x} \in X$. We have

(i) [34, Proposition 3.5] $x^* \in \partial \langle y^*, f \rangle(\bar{x}) \iff (x^*, -y^*) \in \hat{N}((\bar{x}, f(\bar{x})); \text{gph} \, f)$.

(ii) [34, Theorem 1.90] $x^* \in \partial \langle y^*, f \rangle(\bar{x}) \iff (x^*, -y^*) \in N((\bar{x}, f(\bar{x})); \text{gph} \, f)$. 

Lemma 2.2. [34, Corollary 3.43] Let $f : X \rightarrow Y$ be locally Lipschitz at $\bar{x} \in X$, and let $\varphi : Y \rightarrow \mathbb{R}$ be locally Lipschitz around $f(\bar{x})$. Then one has

\begin{equation}
\partial(\varphi \circ f)(\bar{x}) \subset \bigcup_{y^* \in \partial \varphi(f(\bar{x}))} \partial(y^*, f)(\bar{x}).
\end{equation}

3. Approximate Optimality Conditions in Composite Vector Optimization

The aim of this section is to devote to studying necessary and sufficient optimality conditions for (weak) $\varepsilon$-quasi efficient solutions of problem (P). The forthcoming theorem provides a Fritz-John type necessary optimality condition, expressed in terms of the limiting subdifferential, for (weak) $\varepsilon$-quasi efficient solutions of problem (P); the proof is motivated by [8, Theorem 3.1] and [9, Theorem 3.2]. To this aim, we need a fuzzy necessary optimality condition for (weak) $\varepsilon$-quasi efficient solutions in conic vector optimization problems as follows.

Lemma 3.3. For the problem (P) with $X = W = V$ and $F$ and $G$ are identical maps, let $\bar{x} \in e - S^w(P)$. Then, for a given $k \in \mathbb{N}$, one can find $x^{1k} \in B_X(\bar{x}, \frac{1}{k})$, $x^{2k} \in B_X(\bar{x}, \frac{1}{k})$, $x^{3k} \in \Omega \cap B_X(\bar{x}, \frac{1}{k})$, $y^*_k \in K^+$ and $z^*_k \in S^+$ such that $\|y^*_k\| = 1$ and

\begin{align*}
0 & \in \partial(y_k^*, f)(x^{1k}) + \partial(z_k^*, g)(x^{2k}) + \hat{N}(x^{3k}; \Omega) + \left(\langle y_k^*, e \rangle + \frac{1}{k}\right)B_X, \\
\|z_k^*, g(x^{2k})\| & \leq \frac{1}{k}.
\end{align*}

Theorem 3.1. Let $\bar{x} \in e - S^w(P)$. Then, there exist $y^* \in K^+$ and $z^* \in S^+$ with $\|y^*\| + \|z^*\| = 1$, such that

\begin{equation}
0 \in \bigcup_{w^* \in \partial(y^*, f)(f(\bar{x}))} \partial(w^*, f)(\bar{x}) + \bigcup_{v^* \in \partial(z^*, g)(G(\bar{x}))} \partial(v^*, G)(\bar{x}) + \langle y^*, e \rangle B_X + N(\bar{x}; \Omega),
\end{equation}

Proof. We begin by putting $\tilde{f} = f \circ F$ and $\tilde{g} = g \circ G$. On account of $\bar{x} \in e - S^w(P)$, we invoke Lemma 3.3 to assert that for each $k \in \mathbb{N}$ there exist $x^{1k} \in B_X(\bar{x}, \frac{1}{k})$, $x^{2k} \in B_X(\bar{x}, \frac{1}{k})$, $x^{3k} \in \Omega \cap B_X(\bar{x}, \frac{1}{k})$, $y^*_k \in K^+$ with $\|y^*_k\| = 1$ and $z^*_k \in S^+$ such that

\begin{align*}
0 & \in \partial(y_k^*, \tilde{f})(x^{1k}) + \partial(z_k^*, \tilde{g})(x^{2k}) + \hat{N}(x^{3k}; \Omega) + \left(\langle y_k^*, e \rangle + \frac{1}{k}\right)B_X, \\
\|z_k^*, \tilde{g}(x^{2k})\| & \leq \frac{1}{k}.
\end{align*}

Consequently, we find sequences $\{x^{1k}\} \subset X$, $\{x^{2k}\} \subset X$, $\{x^{3k}\} \subset X$, $\{y^*_k\} \subset X$, $\{x^{1k}_k\} \subset X$, $\{y^*_k\} \subset K^+$ with $\|y^*_k\| = 1$ and $\{z^*_k\} \subset S^+$ such that $x^{1k}_k \in \partial(y_k^*, f \circ F)(x^{1k})$, $x^{2k}_k \in \partial(z_k^*, g \circ G)(x^{2k})$, $x^{3k}_k \in \hat{N}(x^{3k}; \Omega)$,

\begin{align*}
0 & \in x^{1k}_k + x^{2k}_k + x^{3k}_k + \left(\langle y_k^*, e \rangle + \frac{1}{k}\right)B_X,
\end{align*}

and

\begin{align*}
x^{1k} \rightarrow \bar{x}, & \quad x^{2k} \rightarrow \bar{x}, \quad x^{3k} \rightarrow \bar{x}, \quad \langle z^*_k, g \circ G(x^{2k})\rangle \rightarrow 0 \text{ as } k \rightarrow \infty.
\end{align*}

Let us note by passing to a subsequence if necessary that $y^*_k \rightarrow \tilde{y}^* \in K^+$ as $k \rightarrow \infty$, where $\|\tilde{y}^*\| = 1$. By our assumptions, we suppose that $f \circ F$ is locally Lipschitz at $\bar{x}$ with a modulus $l_1 > 0$. It then follows from $x^{1k}_k \in \partial(y_k^*, f \circ F)(x^{1k})$ together with [34, Proposition 1.85] that $\|x^{1k}_k\| \leq 1_1 \|y^*_k\| = l_1$ for all $k \in \mathbb{N}$. Hence, as $X$ is a finite-dimensional space, we may assume by taking a subsequence if necessary that $x^{1k}_k \rightarrow x^*_1 \in X$ as $k \rightarrow \infty$. Similarly, let $l_2 > 0$ be a Lipschitz constant of $g \circ G$ around $\bar{x}$, and so,

\begin{align*}
\|x^{2k}_k\| \leq l_2 \|z^*_k\|, \quad \forall k \in \mathbb{N}.
\end{align*}

Let us now consider two the following cases:
(C1): Assume that \( \{z_k^*\} \) is unbounded. There is no loss of generality in assuming that \( \|z^*\| \to \infty \) and \( \frac{x}{\|z_k^*\|} \to z^* \in S^+ \) with \( \|z^*\| = 1 \) as \( k \to \infty \). It stems from (3.5) we have 
\[
\langle \frac{x}{\|z_k^*\|}, (g \circ G)(x_k^2) \rangle \to 0 \quad \text{as} \quad k \to \infty ,
\]
which in turn gives us the equality \( \langle z^*, g(G(\bar{x})) \rangle = 0 \).

In addition, by (3.6), we may assume that \( \frac{x_k}{\|z_k^*\|} \to x_2 \in X \) as \( k \to \infty \). Then, in view of (3.4), there exist \( b_k \in B_X, k \in \mathbb{N} \) such that
\[
(3.7) \quad -\frac{x_{1k}^*}{\|z_k^*\|} - \frac{x_{2k}^*}{\|z_k^*\|} - \frac{(\langle y_k^*, e \rangle + \frac{1}{k} b_k)}{\|z_k^*\|} = \frac{x_{3k}^*}{\|z_k^*\|} \in \hat{N}(x^3_k; \Omega), \quad k \in \mathbb{N}.
\]

Letting \( k \to \infty \) in (3.7) and noticing (2.1), we get
\[
(3.8) \quad -x_2^* \in \hat{N}(\bar{x}; \Omega).
\]

According to Lemma 2.1(i), for each \( k \in \mathbb{N} \), the inclusion \( x_{2k}^* \in \tilde{\mathcal{N}}(z_k^*; g \circ G)(x_{2k}^2) \) amounts to \( (x_{2k}^*, -z_k^*) \in \tilde{\mathcal{N}}(x_{2k}^2; g \circ G)(x_{2k}^2) \); \( \text{gph} (g \circ G) \), and consequently, \( (x_{2k}^*, -z_k^*) \in \tilde{\mathcal{N}}((x_{2k}^2; g \circ G)(x_{2k}^2)); \text{gph} (g \circ G) \). Passing to the limit as \( k \to \infty \) in the preceding inclusion and taking (2.1) into account, we obtain that \( (x_2^*, -z^*) \in \tilde{\mathcal{N}}((\bar{x}, g \circ G)(\bar{x})); \text{gph} (g \circ G) \), which, by virtue of 2.1(ii), is equivalent to
\[
(3.9) \quad x_2^* \in \mathcal{N}(\bar{x}; g \circ G)(\bar{x}).
\]

Combining (3.8) along with (3.9) and by taking \( y^* := 0 \in K^+ \), we arrive at
\[
(3.10) \quad 0 \in \mathcal{N}(y^*, f \circ F)(\bar{x}) + \mathcal{N}(\bar{x}; g \circ G)(\bar{x}) + \langle y^*, e \rangle B_X + N(\bar{x}; \Omega).
\]

(C2): If \( \{z_k^*\} \) is bounded, then we may assume by taking a subsequence if necessary that \( z_k^* \to \bar{z}^* \in S^+ \) as \( k \to \infty \). Due to (3.6), we also have that \( \{x_k^*\} \) is bounded, and so, we may assume without loss of generality that \( x_{2k}^* \to x_2 \in X \) as \( k \to \infty \). As above, we get from the inclusion \( x_{1k}^* \in \tilde{\mathcal{N}}(y_k^*, f \circ F)(x_{1k}^1) \) that \( (x_{1k}^*, -y_k^*) \in \tilde{\mathcal{N}}((x_{1k}^1, f \circ F)(x_{1k}^1)); \text{gph} (f \circ F) \) for all \( k \in \mathbb{N} \). Therefore,
\[
(3.11) \quad \left( \frac{x_{1k}^*}{\|y_k^*\| + \|z_k^*\|}, \frac{-y_k^*}{\|y_k^*\| + \|z_k^*\|} \right) \in \tilde{\mathcal{N}}((x_{1k}^1, f \circ F)(x_{1k}^1)); \text{gph} (f \circ F).
\]

Passing (3.11) to the limit as \( k \to \infty \) and noticing (2.1), we obtain that
\[
\left( \frac{x_1^*}{\|\hat{y}^*\| + \|\hat{z}^*\|}, \frac{-\hat{y}^*}{\|\hat{y}^*\| + \|\hat{z}^*\|} \right) \in \tilde{\mathcal{N}}((\bar{x}, f \circ F)(\bar{x})); \text{gph} (f \circ F),
\]
which amounts to
\[
(3.12) \quad \frac{x_1^*}{\|\hat{y}^*\| + \|\hat{z}^*\|} \in \mathcal{N}(y^*, f \circ F)(\bar{x}),
\]

where \( y^* := \frac{\hat{y}^*}{\|\hat{y}^*\| + \|\hat{z}^*\|} \). Similarly, we obtain that \( \langle z^*, g \circ G(\bar{x}) \rangle = 0 \) and
\[
(3.13) \quad \frac{x_2^*}{\|\hat{y}^*\| + \|\hat{z}^*\|} \in \mathcal{N}(z^*, g \circ G)(\bar{x}),
\]

where \( z^* := \frac{\hat{z}^*}{\|\hat{y}^*\| + \|\hat{z}^*\|} \). On the one hand, (3.4) yields that there exist \( b_k \in B_X, k \in \mathbb{N} \) such that
\[
(3.14) \quad -\frac{x_{1k}^*}{\|y_k^*\| + \|z_k^*\|} - \frac{x_{2k}^*}{\|y_k^*\| + \|z_k^*\|} - \frac{(\langle y_k^*, e \rangle + \frac{1}{k} b_k)}{\|y_k^*\| + \|z_k^*\|} = \frac{x_{3k}^*}{\|y_k^*\| + \|z_k^*\|} \in \hat{N}(x^3_k; \Omega), \quad k \in \mathbb{N}.
\]

Also, we may assume by passing to subsequences if necessary that \( b_k \to b \in B_X \) as \( k \to \infty \). Now, letting \( k \to \infty \) in (3.14) and noticing (2.1), we get the relation
\[
-\frac{x_1^*}{\|\hat{y}^*\| + \|\hat{z}^*\|} - \frac{x_2^*}{\|\hat{y}^*\| + \|\hat{z}^*\|} - \langle \hat{y}^*, e \rangle b \in N(\bar{x}; \Omega).
\]
Combining this with (3.12) and (3.13), (3.10) also holds.

Now, let us note that $F$ and $G$ are locally Lipschitz at $\bar{x}$, by our assumptions, and $\langle y^*, f \rangle$ and $\langle z^*, g \rangle$ are locally Lipschitz at $F(\bar{x})$ and $G(\bar{x})$, respectively. Invoking (3.10) together with the chain rule (2.2) with $\varphi := \langle y^*, f \rangle$ and $\psi := \langle z^*, g \rangle$ proves that (3.3) is valid, and the proof is complete. \qed

Let us now illustrate the usefulness of Theorem 3.1 for verifying necessary conditions for (weak) $e$-quasi efficient solutions of a substantial vector optimization problem via the following example, which is motivated by [9, Example 3.5].

**Example 3.1.** Consider the problem (P) with $\Omega := \mathbb{R}$, $X := \mathbb{R}$, $K := \mathbb{R}_+ \subseteq Y := \mathbb{R}$, $S := \{(y_1, y_2) \in \mathbb{R}^2 \mid y_1 \geq |y_2|\} \subseteq Z := \mathbb{R}^2$, $F(x) := (x^2, x + 1)$, $x \in \mathbb{R}$, $f(w) := (-\frac{1}{2} w_1 + 1, |w_2|)$, $w := (w_1, w_2) \in \mathbb{R}^2$, $G(x) := x + 1$, $x \in \mathbb{R}$, and $g(v) := (\frac{1}{2} v^2 - v, v)$, $v \in \mathbb{R}$. Let us notice that $C = \{v \in \mathbb{R} \mid \frac{1}{2} - \frac{1}{2} v^2 \geq |v + 1|\}$, and let us select $\epsilon := -1 \in C$ and consider $e := (e_1, e_2) \in K$. We can verify by definition that $\bar{x} \in \epsilon - S^w(P)$. By taking $y^* := (\frac{1}{\sqrt{2}}, \frac{1}{\sqrt{2}})$ and $z^* := (0, 0)$. Then, $y^* \in K^+$, $z^* \in S^+$ satisfying $\|y^*\| + \|z^*\| = 1$ and that $\partial \langle y^*, f \rangle(F(\bar{x})) = \{(-\frac{1}{2\sqrt{2}}, \frac{1}{\sqrt{2}} x^*) : x^* \in B_{x} \}$, $\partial \langle z^*, g \rangle(G(\bar{x})) = \{0\}$, $\bigcup_{v^* \in \partial \langle y^*, f \rangle(F(\bar{x}))} \partial \langle w^*, F \rangle(\bar{x}) = \{\frac{1}{\sqrt{2}}\} + \frac{1}{2\sqrt{2}} B_{x}$, $\bigcup_{v^* \in \partial \langle z^*, g \rangle(G(\bar{x}))} \partial \langle v^*, G \rangle(\bar{x}) = \{0\}$ and $N(\bar{x}; \Omega) = \{0\}$. It can be verified that the Fritz-John necessary condition (3.1) in Theorem 3.1 holds.

The following corollary provides a Fritz-John necessary condition for weak Pareto efficiencies of problem (P). This result develops [8, Theorem 3.2] and [9, Theorem 3.4] by letting $\Omega := X$.

**Corollary 3.1.** Let $\bar{x} \in X$ be a weak Pareto solution of problem (P). Then, there exist $y^* \in K^+$ and $z^* \in S^+$ with $\|y^*\| + \|z^*\| = 1$, such that

\[
\begin{cases}
0 \in \bigcup_{w^* \in \partial \langle y^*, f \rangle(F(\bar{x}))} \partial \langle w^*, F \rangle(\bar{x}) + \bigcup_{v^* \in \partial \langle z^*, g \rangle(G(\bar{x}))} \partial \langle v^*, G \rangle(\bar{x}) + N(\bar{x}; \Omega), \\
\langle z^*, g(G(\bar{x})) \rangle = 0.
\end{cases}
\]

**Proof.** Invoking Theorem 3.1 with $\epsilon := 0$, we obtain the desired result. \qed

**Remark 3.1.** Corollary 3.1 reduces to [8, Corollary 3.5]. More exactly, the Clarke subdifferential of $f_k$, $k \in K$, and $g_i$, $i \in I$, at the considered point in framework of [30, Theorem 3.1].

Before we discuss the sufficient conditions for (weak) $e$-quasi efficient solutions of problem (P), let us first define an approximate KKT condition for this problem.

**Definition 3.2.** Let $e \in K$ and let $\bar{x} \in C := \{x \in \Omega \mid (g \circ G)(x) \in -S\}$. One says that $\bar{x}$ is said to satisfy the $e$-approximate KKT condition of problem (P) if (3.3) holds with $y^* \neq 0$.

**Remark 3.2.** In view of Theorem 3.1, observe that a weak $e$-quasi efficient solution $\bar{x}$ satisfies the above-defined approximate KKT condition under the fulfillment of the following constraint qualification: there does not exist $z^* \in S^+$ with $\|z^*\| = 1$ and $\langle z^*, g(G(\bar{x})) \rangle = 0$, such that

\[
(CQ) \quad 0 \in \bigcup_{v^* \in \partial \langle z^*, g \rangle(G(\bar{x}))} \partial \langle v^*, G \rangle(\bar{x}) + N(\bar{x}; \Omega).
\]

It is noteworthy, however, that a feasible point at which the $e$-approximate KKT condition holds needs not be a (weak) $e$-quasi efficient solution in general; see e.g., [4, Example 3.14] in the case of $K := \mathbb{R}_+^p$, $\Omega := \mathbb{R}$, and $F$ and $G$ are identical maps. This fact leads us to employ the following notions of (strictly) approximately generalized convexity (with respect to a cone) for composite vector functions $F$ and $G$. 

Approximate Optimality and Approximate Duality in Nonsmooth Composite Vector Optimization

**Definition 3.3.**

(i) We say that \((f \circ F, g \circ G)\) is \((K \times S)\)-approximately generalized convex on \(\Omega\) at \(\bar{x} \in \Omega\) if for any \(x \in \Omega\), \(y^* \in K^+\), \(z^* \in S^+\), \(\|y^*\| + \|z^*\| = 1\), \(w^* \in \partial \langle y^*, f \rangle(F(\bar{x}))\), \(x^*_1 \in \partial \langle w^*, F \rangle(\bar{x})\), \(v^* \in \partial \langle z^*, g \rangle(G(\bar{x}))\), and \(x^*_2 \in \partial \langle v^*, G \rangle(\bar{x})\), one can find \(v \in -N(\bar{x}; \Omega)^+\) satisfying
\[
\langle y^*, f \circ F \rangle(x) - \langle y^*, f \circ F \rangle(\bar{x}) \geq \langle x^*_1, v \rangle,
\]
\[
\langle z^*, g \circ G \rangle(x) - \langle z^*, g \circ G \rangle(\bar{x}) \geq \langle x^*_2, v \rangle \quad \text{and}
\]
\[
\langle b^*, v \rangle \leq \|x - \bar{x}\|, \quad \forall b^* \in B_X.
\]

(ii) We say that \((f \circ F, g \circ G)\) is \(K\)-strictly \((K \times S)\)-approximately generalized convex on \(\Omega\) at \(\bar{x} \in \Omega\) if for any \(x \in \Omega\), \(y^* \in K^+\), \(z^* \in S^+\), \(\|y^*\| + \|z^*\| = 1\), \(w^* \in \partial \langle y^*, f \rangle(F(\bar{x}))\), \(x^*_1 \in \partial \langle w^*, F \rangle(\bar{x})\), \(v^* \in \partial \langle z^*, g \rangle(G(\bar{x}))\), and \(x^*_2 \in \partial \langle v^*, G \rangle(\bar{x})\), one can find \(v \in -N(\bar{x}; \Omega)^+\) satisfying
\[
\langle y^*, f \circ F \rangle(x) - \langle y^*, f \circ F \rangle(\bar{x}) > \langle x^*_1, v \rangle,
\]
\[
\langle z^*, g \circ G \rangle(x) - \langle z^*, g \circ G \rangle(\bar{x}) \geq \langle x^*_2, v \rangle \quad \text{and}
\]
\[
\langle b^*, v \rangle \leq \|x - \bar{x}\|, \quad \forall b^* \in B_X.
\]

**Remark 3.3.** Given \(\bar{x} \in \Omega\). In view of [8, Proposition 3.9], it can be observed that, if \(\Omega\) is convex, \(\langle y^*, f \rangle\) is convex on \(\Omega\) for every \(y^* \in K^+\), \(z^* \in S^+\) is convex on \(\Omega\) for every \(z^* \in S^+\), \(\langle w^*, F \rangle\) is convex on \(\Omega\) for every \(w^* \in \partial \langle y^*, f \rangle(F(\bar{x}))\) and \(\langle v^*, G \rangle\) is convex on \(\Omega\) for every \(v^* \in \partial \langle z^*, g \rangle(G(\bar{x}))\), then \((f \circ F, g \circ G)\) is \((K \times S)\)-approximately generalized convex on \(\Omega\) at \(\bar{x} \in \Omega\) with \(v := x - \bar{x}\) for each \(x \in \Omega\). Besides, the \(K\)-strictly \((K \times S)\)-approximately generalized convexity of \((f \circ F, g \circ G)\) on \(\Omega\) at \(\bar{x}\) will follows if, in addition, \(\langle y^*, f \rangle\) is strictly convex on \(\Omega\) for every \(y^* \in K^+\) and \(F\) is injective on \(\Omega\) (i.e., \(\forall x_1, x_2 \in \Omega\), \(F(x_1) = F(x_2) \Rightarrow x_1 = x_2\)). Furthermore, [8, Remark 3.10] indicated that the class of approximately generalized convex composite vector functions defined in Definition 3.3 is properly bigger than the one of convex vector functions.

We are now in a position to provide sufficient conditions for (weak) \(e\)-quasi efficient solutions of problem (P) under the satisfaction of the (strictly) approximately generalized convexity.

**Theorem 3.2.** Let \(e \in K\) and assume that \(\bar{x} \in C\) satisfies the \(e\)-approximately KKT condition of problem (P).

(i) If \((f \circ F, g \circ G)\) is \((K \times S)\)-approximately generalized convex on \(\Omega\) at \(\bar{x}\), then \(\bar{x} \in e - S_w(P)\).

(ii) If \((f \circ F, g \circ G)\) is \(K\)-strictly \((K \times S)\)-approximately generalized convex on \(\Omega\) at \(\bar{x}\), then \(\bar{x} \in e - S(P)\).

**Proof.** As \(\bar{x} \in C\) is an \(e\)-approximately KKT point of problem (P), there exist \(y^* \in K^+\setminus\{0\}\), \(z^* \in S^+\), \(w^* \in \partial \langle y^*, f \rangle(F(\bar{x}))\), \(x^*_1 \in \partial \langle w^*, F \rangle(\bar{x})\), \(v^* \in \partial \langle z^*, g \rangle(G(\bar{x}))\), \(x^*_2 \in \partial \langle v^*, G \rangle(\bar{x})\) and \(b^* \in B_X\) such that \(\|y^*\| + \|z^*\| = 1\) and
\[
-(x^*_1 + x^*_2 + \langle y^*, e \rangle b^*) \in N(\bar{x}; \Omega),
\]
\[
\langle z^*, g(G(\bar{x})) \rangle = 0.
\]

To justify (i), we assume by contradiction that \(\hat{x} \notin e - S_w(P)\), and consequently, there is \(\hat{x} \in C\) such that \(\langle f(\hat{x}) - (f \circ F)(\bar{x}) + \|\hat{x} - \bar{x}\| e \in -\text{int } K\). It then follows from [22, Lemma 3.21] that
\[
\langle y^*, (f \circ F)(\hat{x}) - (f \circ F)(\bar{x}) + \|\hat{x} - \bar{x}\| e \rangle < 0.
\]
Due to the approximately generalized convexity of \((f \circ F, g \circ G)\) on \(\Omega\) at \(\bar{x}\), taking into account (3.15) together with the fact that \(\langle y^*, e \rangle \geq 0\), we find \(v \in -N(\bar{x}; \Omega)^+\) satisfying

\[
0 \leq \langle x_1^*, v \rangle + \langle x_2^*, v \rangle + \langle y^*, e \rangle \langle b^*, v \rangle
\leq \langle y^*, f \circ F \rangle(\bar{x}) - \langle y^*, f \circ F \rangle(\bar{x}) + \langle z^*, g \circ G \rangle(\bar{x}) - \langle z^*, g \circ G \rangle(\bar{x}) + \langle y^*, e \rangle \|\bar{x} - \bar{x}\|.
\]

In addition, we have \(\langle z^*, g(G(\bar{x})) \rangle \leq 0\) inasmuch as \(g(G(\bar{x})) \in -S\). Taking (3.16) into account, we now invoke the second inequality in (3.18) to deduce that

\[
0 \leq \langle y^*, (f \circ F)(\bar{x}) - (f \circ F)(\bar{x}) \rangle + \|\bar{x} - \bar{x}\|e,
\]

which contradicts to (3.17), and so the proof of (i) has been established.

Next, we now prove (ii) by the method of contradiction and suppose that \(\bar{x} \notin e - S(P)\). So, we can find \(\bar{x} \in C\) such that \((f \circ F)(\bar{x}) - (f \circ F)(\bar{x}) + \|\bar{x} - \bar{x}\|e \in -K \setminus \{0\}\), which in turn implies that \(\bar{x} \neq \bar{x}\) and

\[
\langle y^*, (f \circ F)(\bar{x}) - (f \circ F)(\bar{x}) \rangle + \|\bar{x} - \bar{x}\|e \leq 0.
\]

Proceeding similarly as in the proof of (i), we arrive at

\[
0 < \langle y^*, (f \circ F)(\bar{x}) - (f \circ F)(\bar{x}) \rangle + \|\bar{x} - \bar{x}\|e,
\]

which is a contradiction to (3.19), and so the proof is complete. \(\square\)

4. Duality for approximate solutions in composite vector optimization

In this section, we address a dual vector problem to the composite vector optimization problem (P) and examine converse and strong dualities assertions for approximate (weak) efficient solutions of (P) and its dual which is formulated in the sense of Mond and Weir [33].

Given \(e \in K\), we consider a dual vector program in connection with the problem (P) as follows:

\[
(D) \quad \max_K \{ \mathcal{L}(z, y^*, z^*) := (f \circ F)(z) \mid (z, y^*, z^*) \in C_D\},
\]

where the feasible set \(C_D\) is given by

\[
C_D := \left\{ (z, y^*, z^*) \in \Omega \times (K^+ \setminus \{0\}) \times S^+ \mid 0 \in \bigcup_{w^* \in \partial(y^*, f)(F(z))} \partial(w^*, F)(z)
+ \bigcup_{v^* \in \partial(z^*, g)(G(z))} \partial(v^*, G)(z) + \langle y^*, e \rangle B_X + N(z; \Omega), \langle z^*, g(G(z)) \rangle \geq 0 \right\}.
\]

The approximate efficient solutions for the dual vector problem (D) are defined in an analogous manner as for the primal problem (P) stated in Definition 1.1.

**Definition 4.4.**

(i) We say that \((\tilde{z}, \tilde{y}^*, \tilde{z}^*) \in C_D\) is an \(e\)-quasi efficient solution of problem (D), denoted by \((\tilde{z}, \tilde{y}^*, \tilde{z}^*) \in e - S(D)\), whenever

\[
\forall (z, y^*, z^*) \in C_D, \: \mathcal{L}(z, y^*, z^*) - \mathcal{L}(\tilde{z}, \tilde{y}^*, \tilde{z}^*) - \|z - y^*, z^* - (\tilde{z}, \tilde{y}^*, \tilde{z}^*)\|e \notin K \setminus \{0\}.
\]

(ii) One say that \((\tilde{z}, \tilde{y}^*, \tilde{z}^*) \in C_D\) is a weak \(e\)-quasi efficient solution of problem (D), denoted by \((\tilde{z}, \tilde{y}^*, \tilde{z}^*) \in e - S_{weak}(D)\), whenever

\[
\forall (z, y^*, z^*) \in C_D, \: \mathcal{L}(z, y^*, z^*) - \mathcal{L}(\tilde{z}, \tilde{y}^*, \tilde{z}^*) - \|z - y^*, z^* - (\tilde{z}, \tilde{y}^*, \tilde{z}^*)\|e \notin \text{int} \: K.
\]

The next theorem describes strong duality relations for (weak) \(e\)-quasi efficient solutions of problem (P) and problem (D).
Theorem 4.3 (Strong Duality). Let $e \in K$ and assume that (CQ) is satisfied at $\bar{x} \in e - S^w(P)$. Then, there exists $(\bar{y}^*, \bar{z}^*) \in K^+ \times S^+$ such that $(\bar{x}, \bar{y}^*, \bar{z}^*) \in C_D$. Furthermore, the following statements hold:

(i) If $(f \circ F, g \circ G)$ is $(K \times S)$-approximately generalized convex on $\Omega$ at $z$ for all $z \in \Omega$, then $(\bar{x}, \bar{y}^*, \bar{z}^*) \in e - S^w(D)$.

(ii) If $(f \circ F, g \circ G)$ is $K$-strictly $(K \times S)$-approximately generalized convex on $\Omega$ at $z$ for all $z \in \Omega$, then $(\bar{x}, \bar{y}^*, \bar{z}^*) \in e - S(D)$.

Proof. In view of Theorem 3.1, it stems from (4.20) that $\bar{x} \in e - S^w(P)$ that there exist $\bar{y}^* \in K^+$ and $\bar{z}^* \in S^+$ with $\|\bar{y}^*\| + \|\bar{z}^*\| = 1$ such that

$$0 \in \bigcup_{w^* \in \partial\langle y^*, f(F(x))\rangle} \partial\langle w^*, F\rangle(\bar{x}) + \bigcup_{v^* \in \partial\langle z^*, g\circ(G(x))\rangle} \partial\langle v^*, G\rangle(\bar{x}) + \langle y^*, e \rangle B_X + N(\bar{x}; \Omega),$$

Since the (CQ) is satisfied at $\bar{x}$, it follows that $\bar{y}^* \neq 0$. So, we conclude that $(\bar{x}, \bar{y}^*, \bar{z}^*) \in C_D$.

We first justify (i). Let $(f \circ F, g \circ G)$ be $(K \times S)$-approximately generalized convex on $\Omega$ at any $z \in \Omega$. Suppose on the contrary that $(\bar{x}, \bar{y}^*, \bar{z}^*) \notin e - S^w(D)$. This means that there exists $(z, y^*, z^*) \in C_D$ such that $\|z, y^*, z^*\| - (\bar{x}, \bar{y}^*, \bar{z}^*)\| e \in \text{int } K$, which in turn is equivalent to the assertion

$$0 \leq \langle x^*_1, v \rangle + \langle x^*_2, v \rangle + \langle y^*, e \rangle \langle b^*, v \rangle$$

$$0 \leq \langle y^*, (f \circ F)(\bar{x}) \rangle + \langle y^*, (f \circ F)(z) \rangle - (\bar{x}, \bar{y}^*, \bar{z}^*)\| e - (f \circ F)(z) \| < 0.$$

By virtue of (4.20), we deduce from (4.21) that, for such $\bar{x}$, there exists $v \in -N(\bar{x}; \Omega)^+$ such that

$$0 \leq \langle x^*_1, v \rangle + \langle x^*_2, v \rangle + \langle y^*, e \rangle \langle b^*, v \rangle$$

$$\leq \langle y^*, (f \circ F)(\bar{x}) \rangle - \langle y^*, (f \circ F)(z) \rangle + \langle z^*, g \circ G\rangle(\bar{x}) - \langle z^*, g \circ G\rangle(z) + \langle y^*, e \rangle\| \bar{x} - z \|,$$

where we should remind that $\langle y^*, e \rangle \geq 0$. Due to the feasibility of $\bar{x}$, we have $\langle z^*, g \circ G\rangle(\bar{x}) \leq 0$. This together with (4.22) and (4.24) in turn gives us that

$$0 \leq \langle y^*, (f \circ F)(\bar{x}) \rangle + \langle \bar{x} - z, e - (f \circ F)(z) \rangle \leq 0.$$

Now, combining (4.23) and (4.25), we arrive at

$$\langle y^*, e \rangle \| (z, y^*, z^*) - (\bar{x}, \bar{y}^*, \bar{z}^*)\| < \langle y^*, e \rangle \| \bar{x} - z \|,$$

which is a contradiction. Hence, $(\bar{x}, \bar{y}^*, \bar{z}^*) \in e - S^w(D)$.

Now, we prove (ii). Let $(f \circ F, g \circ G)$ be $K$-strictly $(K \times S)$-approximately generalized convex on $\Omega$ at any $z \in \Omega$ and assume that $(\bar{x}, \bar{y}^*, \bar{z}^*) \notin e - S(D)$. Then, one can find $(z, y^*, z^*) \in C_D$ such that

$$0 \leq \langle y^*, (f \circ F)(\bar{x}) \rangle + \langle \bar{x} - z, e - (f \circ F)(z) \rangle \leq 0,$$

Observe that (4.26) infers to $\bar{x} \neq z$. Moreover, we also have (4.21) and (4.22) by the dual feasibility of $(z, y^*, z^*)$. Now, it holds by (4.26) that

$$\langle y^*, (f \circ F)(\bar{x}) \rangle + \langle z, y^*, z^* \rangle - (\bar{x}, \bar{y}^*, \bar{z}^*)\| e - (f \circ F)(z) \| \leq 0.$$
and, by definition of the dual cone and the $K$-strictly $(K \times S)$-approximately generalized convexity of $(f \circ F, g \circ G)$ on $\Omega$ at $z \in \Omega$, we conclude by (4.21) that for $\bar{x}$ above, one can find $v \in -N(\bar{x};\Omega)^+$ such that

$$0 \leq \langle x_1^*, v \rangle + \langle x_2^*, v \rangle + \langle y^*, e \rangle \langle b^*, v \rangle$$

(4.28) $$< \langle y^*, F(\bar{x}) \rangle - \langle y^*, F(\bar{z}) \rangle + \langle z^*, g_0(G) \rangle (\bar{x}) - \langle z^*, g_0(G) \rangle (\bar{z}) + \langle y^*, e \rangle \| \bar{x} - z \|.$$ 

Since as $(z^*, g_0(G))(x) \leq 0$ shown above, (4.22) together with (4.28) gives us that

$$0 < \langle y^*, (f \circ F)(\bar{x}) \rangle + \| \bar{x} - z \| e - (f \circ F)(\bar{z})).$$

This together with (4.27) establishes a contradiction. So, $(\bar{x}, \bar{y}^*, z^*) \in e - S(D)$.

\[\Box\]

Remark 4.4. It is worth noting that the (CQ) imposed in Theorem 4.3 plays a key role to confirm the existence of multiplier vectors $(\bar{y}^*, \bar{z}^*) \in K^+ \times S^+$ corresponding to $\bar{x} \in e - S^w(P)$ so that $(\bar{x}, \bar{y}^*, \bar{z}^*) \in C_D$. Note also that the conclusion of Theorem 4.3 may go awry if the approximate generalized convexity of $(f \circ F, g \circ G)$ on $\Omega$ at $\bar{x}$ is violated. These facts will demonstrate in Example 4.2 and Example 4.3, respectively.

Example 4.2. Let $\Omega := R, K := R^2_+$ and $S := (0, +\infty)$. Considering the problem (P), where $F(x) := (x+1, x+1), x \in R, f(w) := (w_1, w_2), w := (w_1, w_2) \in R^2, G(x) := x+1, x \in R$, $g(v) := v^2, v \in R$. It is easy to verify that $C = \{-1\}$, and hence, $\bar{x} := -1 \in e - S^w(P) = e - S(P)$ with any $e \in K$; see e.g., [9, Example 4.3]. It could be convenient to observe that $(f \circ F, g \circ G)$ is $(K \times S)$-approximately generalized convex on $\Omega$ at $y$ for all $y \in \Omega$.

Now the dual vector problem $(D)$ with $e := (1/2, 1/2) \in K$. We can verify that there does not exist $(y^*, z^*) \in K^+ \times S^+$ fulfilling $(\bar{x}, y^*, z^*) \in C_D$. This means that the conclusion of Theorem 4.3 fails to hold in this case. The reason is that the (CQ) at $\bar{x}$ was violated.

Example 4.3. Let $\Omega := R^+, K := R^2_+$ and $S := (0, +\infty)$. We consider the problem (P), where $F(x) := (x-2)^2 + 1, x \in R, f(w) := (w, w^2 + 2w - 1), w \in R, G(x) := x - 1, x \in R$, $g(v) := -|v|, v \in R$. Then, $C := [1, +\infty)$, and let us select $\bar{x} := 1 \in C$. It can be verified that $\bar{x} \in e - S^w(P)$ for any $e \in K$; see e.g., [9, Example 4.4] and the (CQ) is satisfied at $\bar{x}$. Now, let us consider the dual problem $(D)$. Theorem 4.3 yields that there exist $\bar{y}^* \in (y_1^*, y_2^*) \in K^+$ and $\bar{z}^* \in S^+$ such that $(\bar{x}, \bar{y}^*, \bar{z}^*) \in C_D$. Choosing $z := 2 \in \Omega$, $y^* := (1, 1) \in K^+$, and $z^* := 0 \in S^+$, we can see that $(z, y^*, z^*) \in C_D$. By selecting $e := (e_1, e_2) \in K$ with $e_1 < \Vert (\bar{x}, y^*, z^*) \Vert,$ $e_2 < \Vert (\bar{x}, z, y^*, z^*) \Vert,$ it can be checked that $(f \circ F)(z) - (f \circ F)(\bar{x}) - \Vert (z, y^*, z^*) \Vert - \Vert (\bar{x}, \bar{y}^*, \bar{z}^*) \Vert e \in \text{int } K,$ which is nothing else than $(\bar{x}, \bar{y}^*, \bar{z}^*) \notin e - S^w(D)$. This shows that the conclusion of Theorem 4.3 fails since $(f \circ F, g \circ G)$ is not $(K \times S)$-approximately generalized convex on $\Omega$ at $z$.

We close this paper by presenting converse-like duality relations for (weak) $e$-quasi efficient solutions of problem (P) and problem (D).

Theorem 4.4. Let $(\bar{x}, y^*, z^*) \in C_D$ be such that $\bar{x} \in C$.

(i) If $(f \circ F, g \circ G)$ is $(K \times S)$-approximately generalized convex on $\Omega$ at $\bar{x}$, then $\bar{x} \in e - S^w(P)$.

(ii) If $(f \circ F, g \circ G)$ is $K$-strictly $(K \times S)$-approximately generalized convex on $\Omega$ at $\bar{x}$, then $\bar{x} \in e - S(P)$.

Proof. Since $(\bar{x}, y^*, z^*) \in C_D$, we have that $y^* \in K \setminus \{0\}$, $z^* \in S^+$ and

$$0 \in \cup_{0 \in \partial (\bar{x}, F)} \partial (w^*, F)(\bar{x}) + \cup_{v^* \in \partial (z^*, g \circ G)(\bar{x})} \partial (v^*, G)(\bar{x}) + \langle y^*, e \rangle B_X + N(\bar{x}; \Omega),$$

(4.29) $$\langle z^*, g(G(\bar{x})) \rangle \geq 0.$$
Let us notice, as \( \bar{x} \in C \), i.e., \( (g \circ G)(\bar{x}) \in -S \), that \( \langle z^*, g(G(\bar{x})) \rangle \leq 0 \). Consequently, \( \langle z^*, g(G(\bar{x})) \rangle = 0 \). Note in addition that as \( y^* \in K \setminus \{0\} \), we can put \( \bar{y}^* = \frac{y^*}{\|y^*\| + \|z^*\|}, \bar{z}^* = \frac{z^*}{\|y^*\| + \|z^*\|} \), and so, \( \bar{y}^* \in K^+ \setminus \{0\}, \bar{z}^* \in S^+ \) and \( \|\bar{y}^*\| + \|\bar{z}^*\| = 1 \). It can be observed that (4.29) also holds if \( y^* \) and \( z^* \) are replaced by \( \bar{y}^* \) and \( \bar{z}^* \), respectively. So, in view of Definition 3.2, we arrive at the conclusion that \( \bar{x} \) satisfies the \( \epsilon \)-approximate KKT condition of problem (P). The rest of the proof follows by applying Theorem 3.1.
